(54) Process and arrangement for actuation of a motor vehicle's braking system.

(57) The invention relates to a process and arrangement designed, through braking, to keep constant the speed of a motor-vehicle when travelling on downhill slopes. With the aim of producing simple actuation and deactivation of the constant speedkeeping function, the invention is characterized principally in that the constant speedkeeping function commences upon actuation of a driver-activated brake control (17). In connection with this, the lowest vehicle speed is stored as a target value within the memory of a control unit (1). The actual vehicle speed is then regulated towards the target value through activation of the vehicle brakes (4). Only once an ordinary driver-activated control (19) is activated, is the specified regulation towards the target value suspended.

Description

Process and arrangement for actuation of a motor-vehicle's braking system

The invention relates to a process according to the preamble of Patent Claim 1, as well as an arrangement for implementing the process according to the preamble of Patent Claim 6.

State of the art

In order to be able to achieve constant speed-keeping for a motor-vehicle on downhill slopes, regulation of the vehicle's brakes towards a target speed selected by the driver is already known.

In the case of heavier motor-vehicles, there are used in this connection various types of auxiliary brakes over and above the vehicle's ordinary wheel brakes. These auxiliary brakes can be designed in such cases with a forced cooling system which allows for prolonged application of the auxiliary brakes without the vehicle's main brakes being used. As a result, the main brakes, which conventionally comprise friction brakes of the disc brake or drum brake type, are prevented from overheating, with the associated risk of brake failure. With the use of auxiliary brakes, increased operating safety is thus obtained in the braking system, since the auxiliary brakes are advantageously used for constant speedkeeping purposes and for moderate decelerations, whilst the vehicle's main brakes are saved for violent brakings provoked by unexpected disturbances in the traffic flow.

Systems for constant speedkeeping on downhill slopes by the regulation of auxiliary brakes are previously known through, for example, patent specifications US.A. 4,485,444, US.A. 4,477,124 and US.A. 4,462,479, in which systems built up of logic circuits, for example in the form of a micro-computer, regulate the brakes towards a target speed set by the driver.

The known constant speedkeeping systems are actuated by a driver-activatable control system which is used exclusively for this purpose. This control system can, for example, be disposed upon the steering wheel console in the form of a lever or a rotary control or, in certain cases, a foot-operated control over and above the vehicle's ordinary foot pedals for accelerator, brakes and clutch. Constant speed keeping systems have also been proposed, actuated through some form of push-button programming by the driver.

Summary of the invention

The object of the present invention is to allow an automatic constant speedkeeping function on downhill slopes which will take effect once the driver has actuated an ordinary service brake control for the main braking system of the vehicle. It is thus possible to omit an extra operating control system for the driver which would be exclusively operated for actuation of the constant speedkeeping function and which, additionally, would increase the number of driver controls and the complexity of the driver's environment. To this end, the process according to the invention is distinguished by the distinctive

features specified in the characterizing part of Claim 1 and the arrangement according to the invention by the distinctive features specified in the characterizing part of Claim 6.

In an embodiment of the process according to the invention, the disengagement of the constant speedkeeping system is actuated in a manner known per se by an ordinary control for regulation of the motor-vehicle's load. Consequently, a constant speedkeeping function is obtained totally without either extra actuation or extra deactuation controls.

In a further advantageous embodiment, the downward regulation of the constant speedkeeping function towards a target value is principally effected by the fact that the vehicle's auxiliary brakes are activated while the vehicle's ordinary wheel brakes are not actuated or, alternatively, are partly actuated by an ordinary service brake control partially actuated by the driver.

Other distinguishing features will emerge from the appended claims and from the subsequent description made with reference to the attached figures.

Brief description of the figures

Figure 1 shows a basic structural design of a braking system according to the invention.

Figure 2 shows a flow-chart relating to the brake actuation program.

Description of an exemplary embodiment

Figure 1 illustrates a basic arrangement incorporating those components necessary for the invention. Other monitoring devices or regulating devices which form part of a complete braking system for motor-vehicles, but which are not necessary for an understanding of the invention, are omitted.

The braking system incorporates a logic circuit which, in the exemplary embodiment, comprises a microcomputer 1, hereinafter referred to as the CPU. The system receives a power supply from a battery 6 via a feed cable 10, to which are connected cables 11, 12, 13. These are in turn connected respectively to the CPU, a brake pedal transmitter 2 and an accelerator pedal 3. The CPU is earthed via cable 29. The transmitters 2, 3 consist of limit contacts 16, 18 which are connected to each foot pedal control and which are only open when the foot pedal controls 17, 19 respectively are at rest. Consequently, as a result of these contacts, the CPU receives signals via cables 14, 15 whenever the accelerator pedal or brake pedal is activated.

The CPU continuously monitors the vehicle's speed through a speed transmitter 5. The speed transmitter is suitably a frequency transmitter 30 of the inductive type, connected to the CPU via cables 31, 32, and which, through rotating gear rings or hollow rings on, for example, an output shaft in the vehicle's gearbox, transmits an alternating voltage, the frequency of which is proportional to the speed. The CPU is also able, through changes in the

frequency, to calculate the vehicle's rate of acceleration.

Depending upon the incoming signals from the brake pedal transmitter 2, the accelerator pedal transmitter 3 and the speed transmitter 5, the CPU then actuates the brake regulating device 4.

According to the invention, the CPU contains a memory unit 40 within which the CPU stores a value representing the vehicle's lowest instantaneous speed, monitored by the speed transmitter 5 during the time in which the brake pedal 17 is activated and the contact 16 is closed. Following activation of the brake pedal, the CPU uses the speed value stored within the memory 40 as a speedkeeping target value. In the preferred embodiment, the target value is stored in a register address within the CPU intended for the target value and the conditions for the target value monitoring and fresh inputting of a new target value are provided by the CPU's software. The same functions can also of course be obtained with a control unit built up from logic circuits. By means of the abovementioned arrangement, there is thus formed a constant speedkeeping target value which, in a manner later described, is used for regulation of the vehicle's braking device 4 whenever the vehicle speed exceeds the target value.

The CPU also contains at least one resetting device which, in the exemplary embodiment, comprises the accelerator pedal transmitter 3. This device, upon being activated, transmits a signal through cable 15, whereupon the CPU suspends the constant speedkeeping function. This can suitably occur as a result of the target value within the CPU register being allocated an unreasonably high value substantially in excess of the vehicle's maximum speed, which means that the vehicle's monitored speed cannot exceed this fictitious target value. When the system, following actuation of the brakes, has once again received a real target value stored within the memory, the braking device will be applied as soon as the vehicle's speed exceeds the target value, whereas the constant speedkeeping function ceases once the accelerator pedal is re-actuated.

The flow diagram in Figure 2 illustrates how the constant speedkeeping function is obtained according to a program stored within the CPU. The program is divided into 3 main sections, A,B,C. The first section A produces a function in which any actuation of the brakes is monitored and a target value V_m is set at the vehicle's lowest speed. In a comparison stage 40, monitoring is carried out to determine whether the brake pedal 17 is actuated, which a signal B on the cable 14 transmits. If a signal is present on the cable 14, then the program proceeds to the operation stage 41, in which a brake flag Bx within the CPU register is set high, whereupon the program proceeds to a comparison stage 42, in which the vehicle's speed V is compared with the target value V_m within the CPU register. If the vehicle speed V is lower than the target value V_m , the program goes on to the operation stage 43, in which the vehicle speed V is inputted as a new target value V_m .

There then follows the second section B of the

program, in which a resetting function is obtained if the accelerator is actuated. In the comparison stage 44, monitoring is carried out to determine whether the accelerator pedal 19 is actuated, which a signal TP on the cable 15 transmits. If a signal is present on the cable 15, then the program proceeds to the operation stage 45a, in which the brake flag Bx within the CPU register is set low, whereupon the program proceeds to the operation stage 45b, in which the target value V_m is allocated the abovementioned unreasonably high value for the vehicle.

After the program sections A and B there follows the brake control function C itself, for obtaining constant speedkeeping on downhill slopes. This function is only actuated however if the brake flag Bx is high, which is the case if the brake pedal has been actuated without accompanying or simultaneous actuation of the accelerator pedal. Program section C commences in the comparison stage 46, in which monitoring of the status of the brake flag Bx is carried out. If the brake flag Bx is high, the program proceeds to the comparison stage 47, in which the vehicle's speed is compared against the target value V_m obtained from function A. If the vehicle speed V is greater than the target value V_m , the program then proceeds to the operation stage 48. In stage 48, the vehicle's braking device 4 is applied, designated in the figure as BR, after which the program goes on to the operation stage 49. The program also goes to this stage if, in stage 47, the vehicle speed V was found to be less than the target value V_m . Stage 49 contains a control routine MOD, in which both the vehicle's deceleration and acceleration are checked whenever a braking procedure is initiated. For smooth brake control, the brake application level can be adjusted downwards if the deceleration exceeds defined limit values and can be adjusted upwards if the acceleration exceeds other defined limit values.

Stage 48 can itself contain a number of sub-elements, in which the brake application level within the vehicle's braking device 4 is regulated in proportion to the exceeded target value. The braking device 4 can advantageously comprise an auxiliary brake in the vehicle's drive line, i.e. in the power transmission between engine and drive gear, in the form of a hydrodynamic retarder or an electrical eddy current brake. These can be primarily regulated in a plurality of braking stages, after which, in the case of major braking requirements, a conventional exhaust brake connected to the engine can also be actuated. The exemplary embodiment in Figure 1 shows an arrangement with an exhaust-gas actuator 25 and a retarder with three braking effect stages 26-28. The first braking effect stage 26 yields a braking torque which has been tailored to the vehicle and to low braking requirements, whereas braking stages 27 and 28 yield progressively increasing braking torques. With a braking device set-up of this kind, the CPU can then regulate the braking effect stage 26 in the event of the speedkeeping target value being moderately exceeded, whereas stages 27-28, plus 25, are regulated in proportion to the degree by which the target value V_m is exceeded.

If program section C in stage 46 detects that the brake flag Bx is low, which is the case where the accelerator pedal has been actuated without subsequent brake pedal actuation, the program then proceeds to stage 50. This disengages the brakes, designated in the figure as BR-R, which the program might have actuated in program stage 48 upon prior running of the control program.

The program 40-49/50 is suitably run by the CPU as an interrupt routine a number of times per second. Each stage takes something in the order of a few microseconds in terms of running time. Since the formation of a new speed value V for the vehicle through the frequency transmitter 30 calls for a certain minimum time, it is this time which determines the system's response time for brake regulation. On the other hand, the brake regulation is suspended through an accelerator pedal starting rheostat with a response time corresponding to the interrupt interval. The vehicle's inertia is so great, however, that the brake regulation by the driver will be felt to be continuous.

The above description of an exemplary embodiment of the invention should not be regarded as limiting the same, but rather, within the framework of the concept of the invention and the attached Patent Claims, it can be modified in a plurality of embodiments.

Claims

1. Process designed, through braking, to keep constant the speed of a motor-vehicle when travelling on downhill slopes, characterized in that upon actuation of a driver-activated brake-control (17), the lowest instantaneous vehicle speed which has been developed during the entire brake control actuation is registered as a speedkeeping target value (Vm), that when the vehicle's current speed (V) exceeds the speedkeeping target value, the vehicle's braking is controlled to regulate the speed towards the specified target value, and that the specified regulation is only suspended once a driver-activatable signal (TP) has been registered.

2. The process according to Patent Claim 1, characterized in that the driver-activatable signal (TP) which suspends the constant speed-keeping function is obtained when an ordinary driver-activated control (19) for regulation of the engine load is not at rest.

3. The process according to Patent Claim 2, characterized in that the downward adjustment of the speed towards the target value (Vm) is not effected through activation of ordinary wheel brakes on the vehicle, but instead through the activation of an auxiliary brake system (25-28) disposed within the vehicle's drive line.

4. The process according to Patent Claim 3, characterized in that the auxiliary brake system contains a primary auxiliary brake (26-28) which

comprises a hydrodynamic brake disposed within the drive line.

5. The process according to Patent Claim 3, characterized in that the auxiliary brake system contains a secondary auxiliary brake (25) which comprises an exhaust brake disposed within the car-engine's exhaust system, which is regulated to effect braking whenever the primary brake is unable to reduce the vehicle's speed down to the speedkeeping target value.

6. Arrangement for constant speed keeping of a motor-vehicle when travelling on downhill slopes through regulation of the vehicle's braking device (4) via a control unit (1) which, by means of monitoring devices (2,3,5), recognises at the very least the vehicle's speed, the brake control position and the position of an additional vehicle control (19), so as to bring about disengagement of the constant speed-keeping system, characterized in that the brake control comprises the vehicle's ordinary service brake control (17) and that the control unit (1) contains a memory for storage of the lowest vehicle speed which the vehicle has or has had during simultaneous signalling from the monitoring device (2) for the position of the brake control (17) indicating that the brake control (17) is not at rest, towards which lowest vehicle speed the control unit (1) brakes the vehicle by virtue of the fact that signals regulate the vehicle's braking device (4) whenever the recognised vehicle speed exceeds the stored lowest vehicle speed and until the monitoring device (3) for the additional vehicle control yields a signal for the disengagement of the constant speedkeeping system.

7. Arrangement according to Patent Claim 6, characterized in that the control unit (1) actuates an auxiliary braking system containing a primary auxiliary brake (26-28) which comprises a hydrodynamic brake disposed within the vehicle's drive line.

8. Arrangement according to Patent Claim 6, characterized in that the control unit (1) actuates an auxiliary braking system containing a primary auxiliary brake (26-28) which comprises an eddy current brake disposed within the vehicle's drive line.

9. Arrangement according to Patent Claim 6, characterized in that the control unit (1) actuates an auxiliary braking system containing a primary auxiliary brake (26-28) which comprises a friction brake disposed within the vehicle's drive line.

10. Arrangement according to one of Patent Claims 7-9, characterized in that the auxiliary braking system contains a secondary auxiliary brake (25) which comprises an exhaust brake disposed within the vehicle engine's exhaust system which is directed to brake whenever the primary brake (26-28) is unable to reduce the vehicle's speed down to the speedkeeping target value.

54 Process and arrangement for actuation of a motor vehicle's braking system.

57 The invention relates to a process and arrangement designed, through braking, to keep constant the speed of a motor-vehicle when travelling on downhill slopes. With the aim of producing simple actuation and deactuation of the constant speed-keeping function, the invention is characterized principally in that the constant speedkeeping function commences upon actuation of a driver-activated brake control (17). In connection with this, the lowest

vehicle speed is stored as a target value within the memory of a control unit (1). The actual vehicle speed is then regulated towards the target value through activation of the vehicle brakes (4). Only once an ordinary driver-activated control (19) is activated, is the specified regulation towards the target value suspended.
